Sequence Encoding

Basic Attention

Representations of Variable Length Data

- ⦿ Input: word sequence, image pixels, audio signal, click logs
- ⦿ Property: continuity, temporal, importance distribution
- ⦿ Example
 - ✓ Basic combination: average, sum
 - ✓ Neural combination: network architectures should consider input domain properties
 - CNN (convolutional neural network)
 - RNN (recurrent neural network): temporal information

Network architectures should consider the input domain properties

4 Recurrent Neural Networks

- Learning variable-length representations
 - ✓ Fit for sentences and sequences of values
- Sequential computation makes parallelization difficult
- No explicit modeling of long and short range dependencies

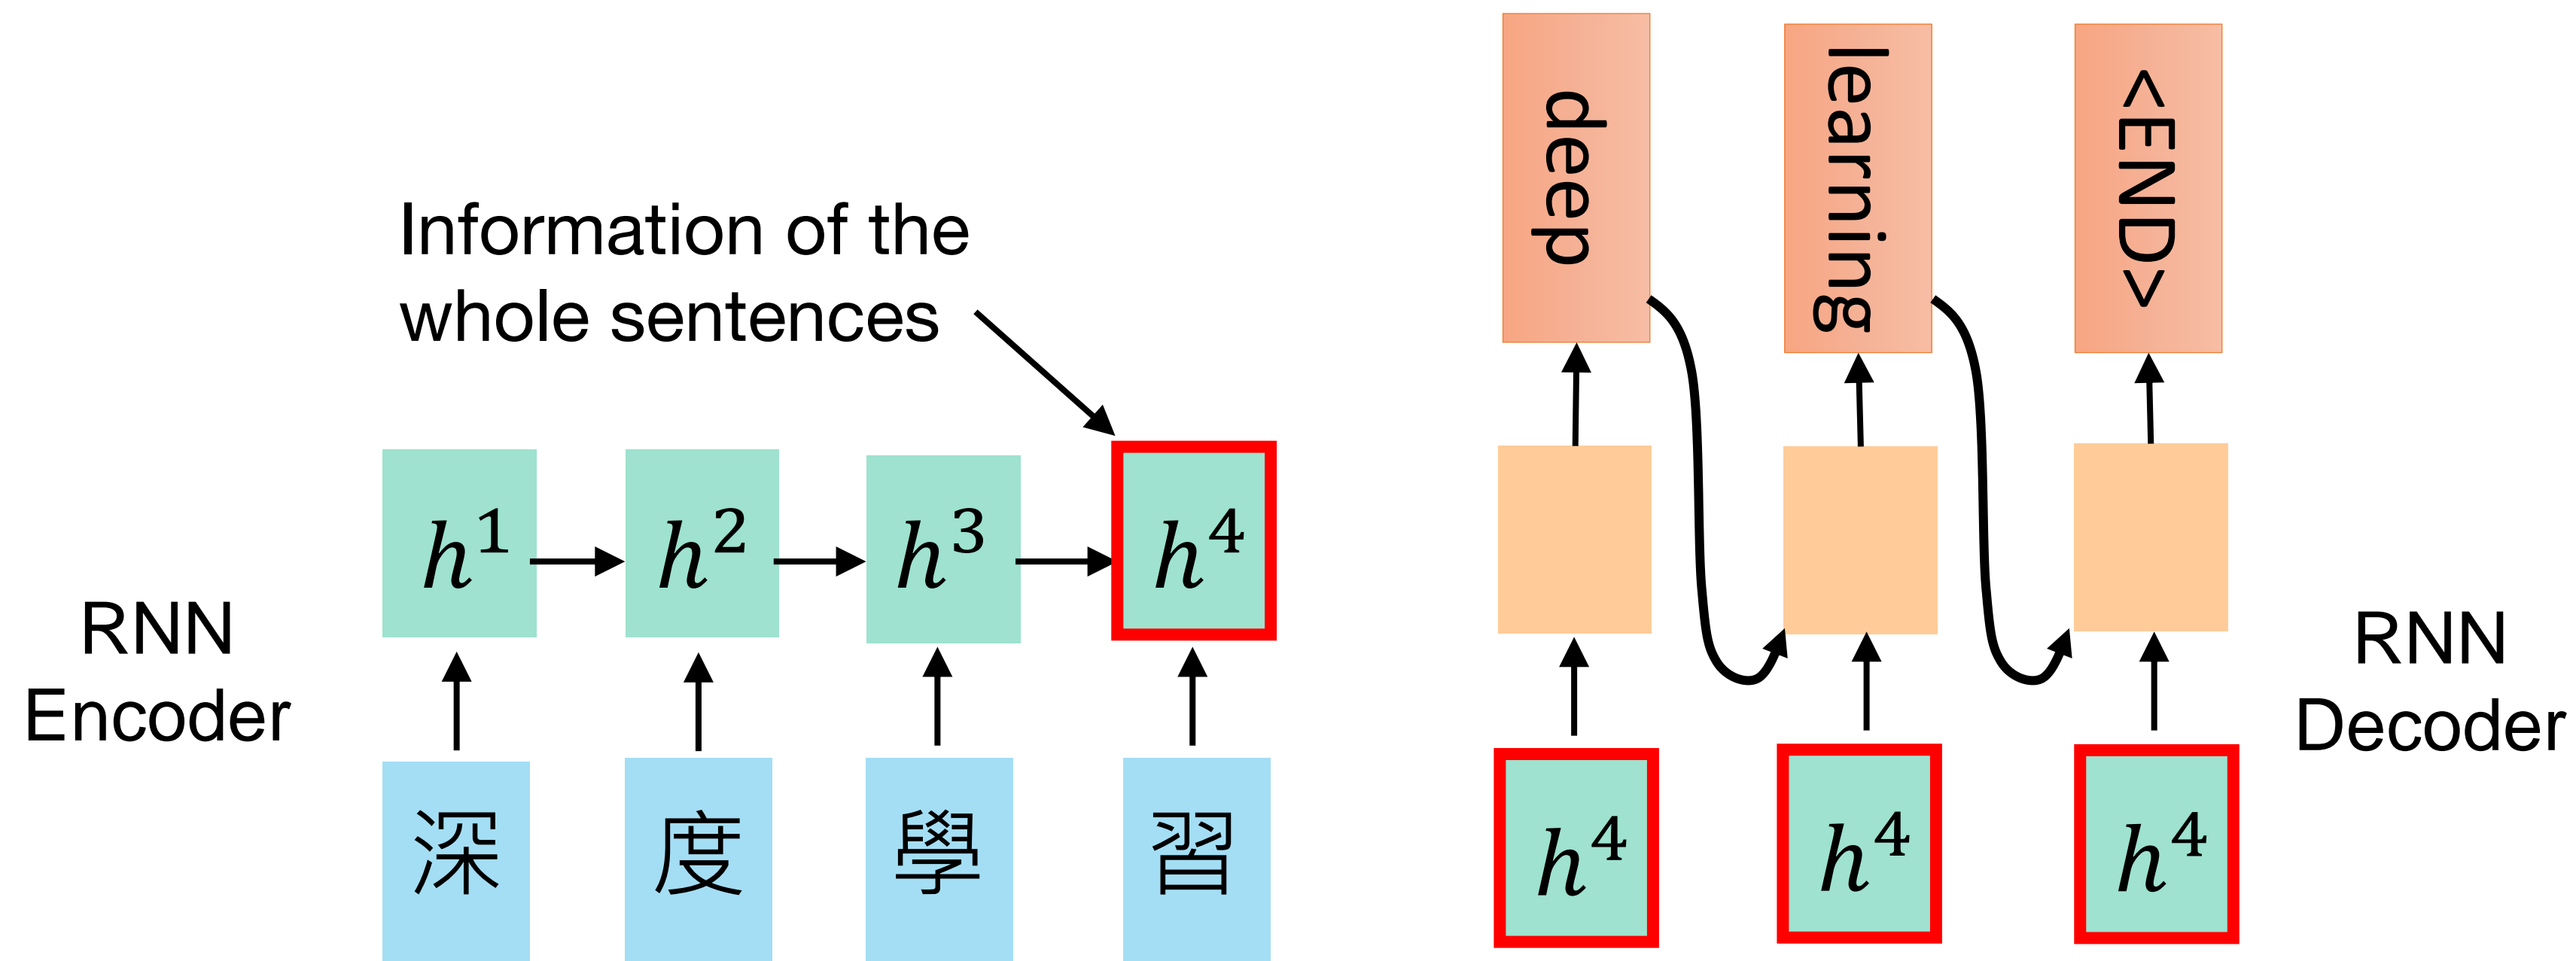

Convolutional Neural Networks

- Easy to parallelize
- Exploit local dependencies
 - ✓ **Long-distance** dependencies require many layers

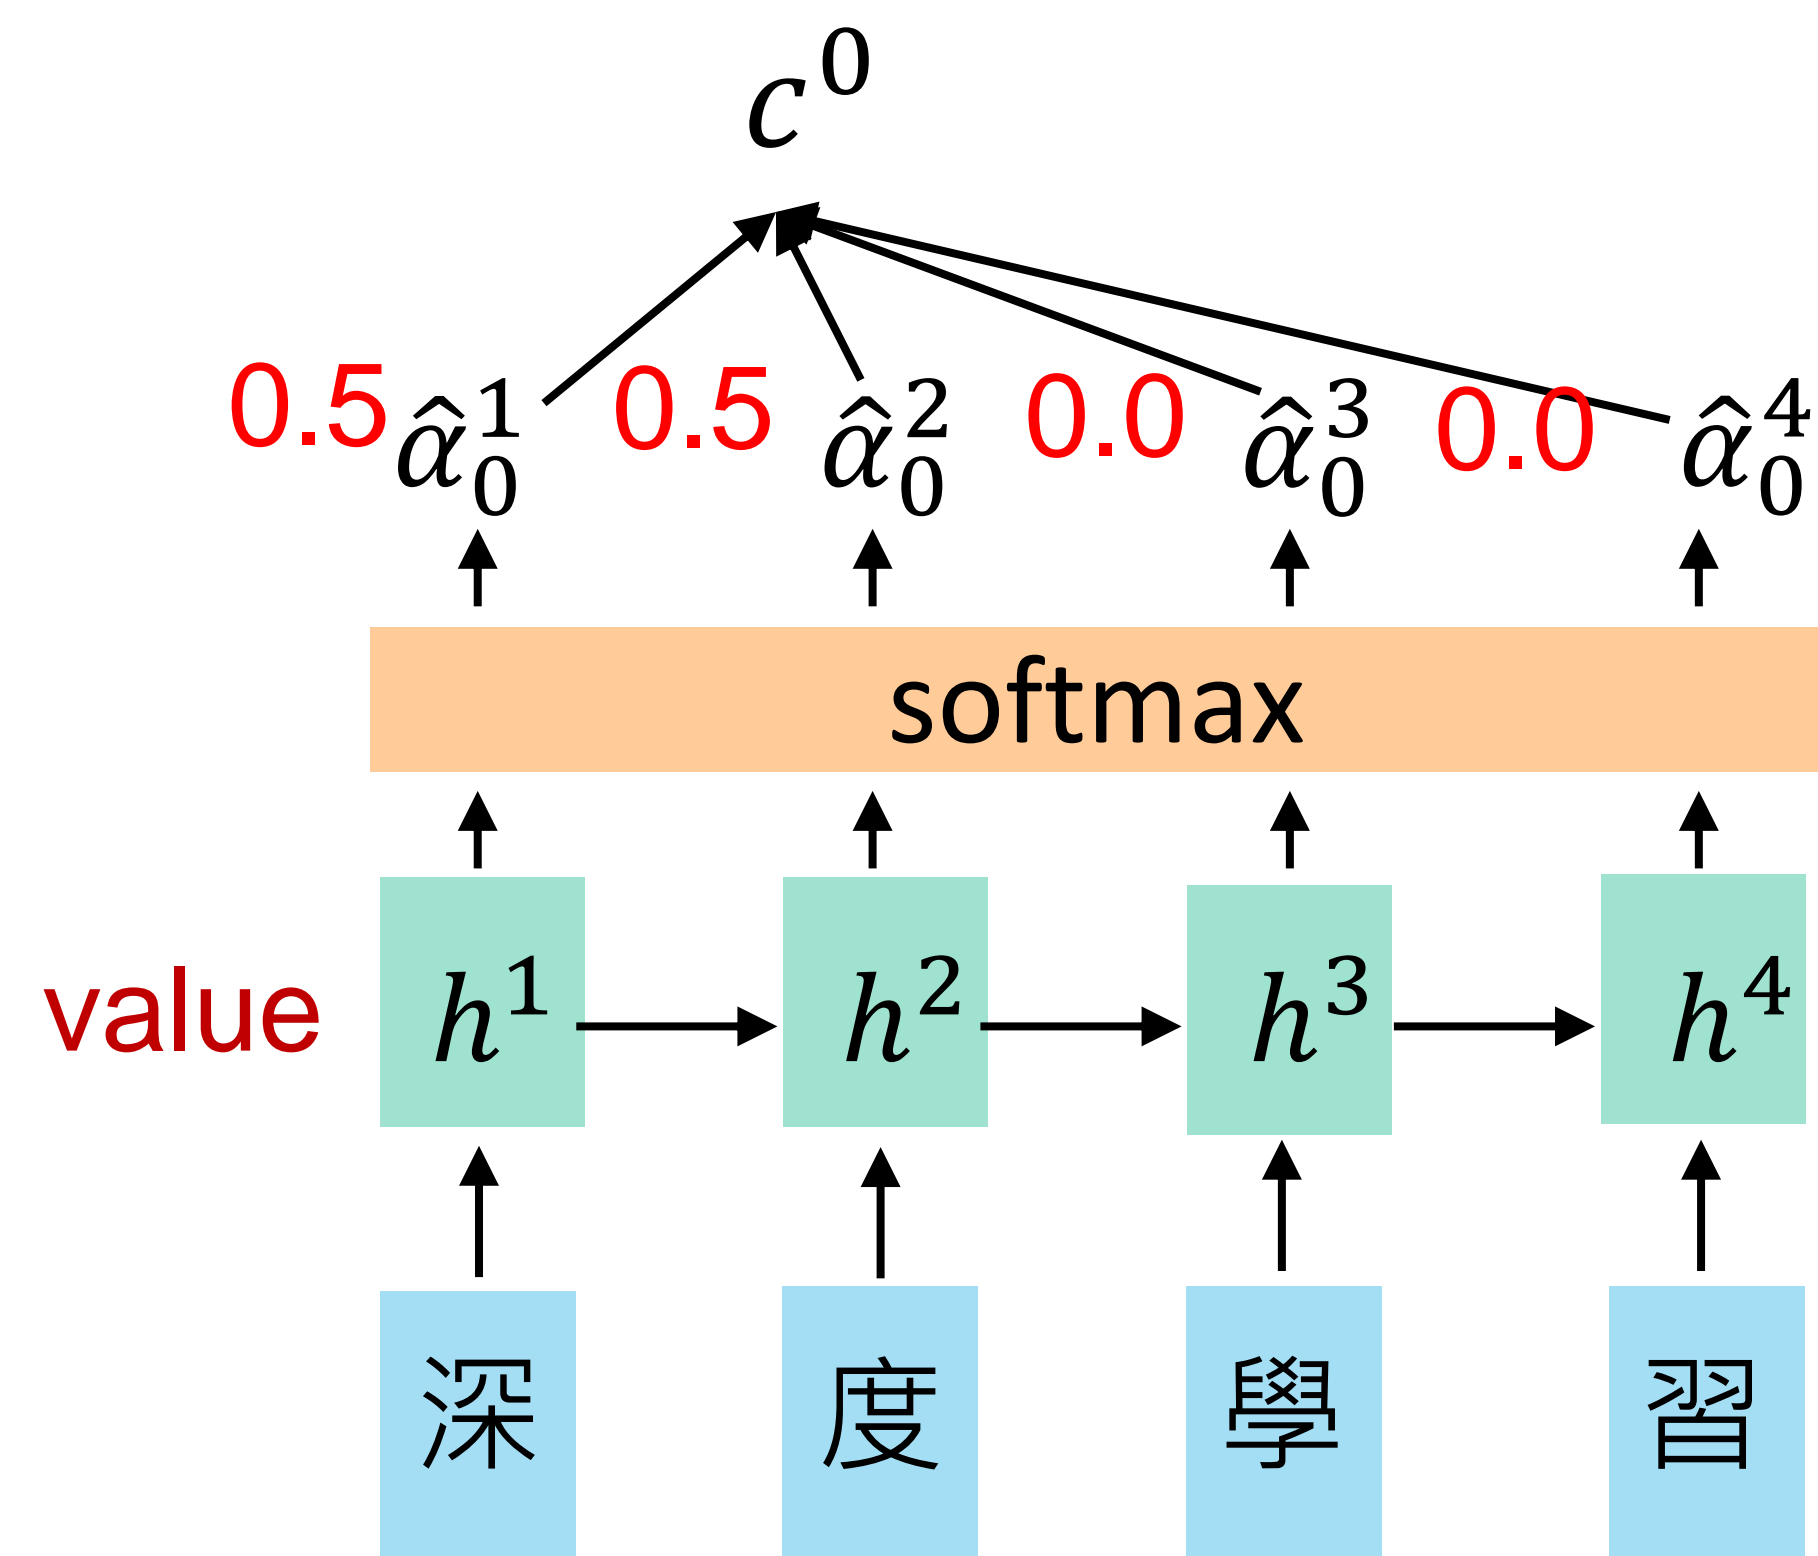

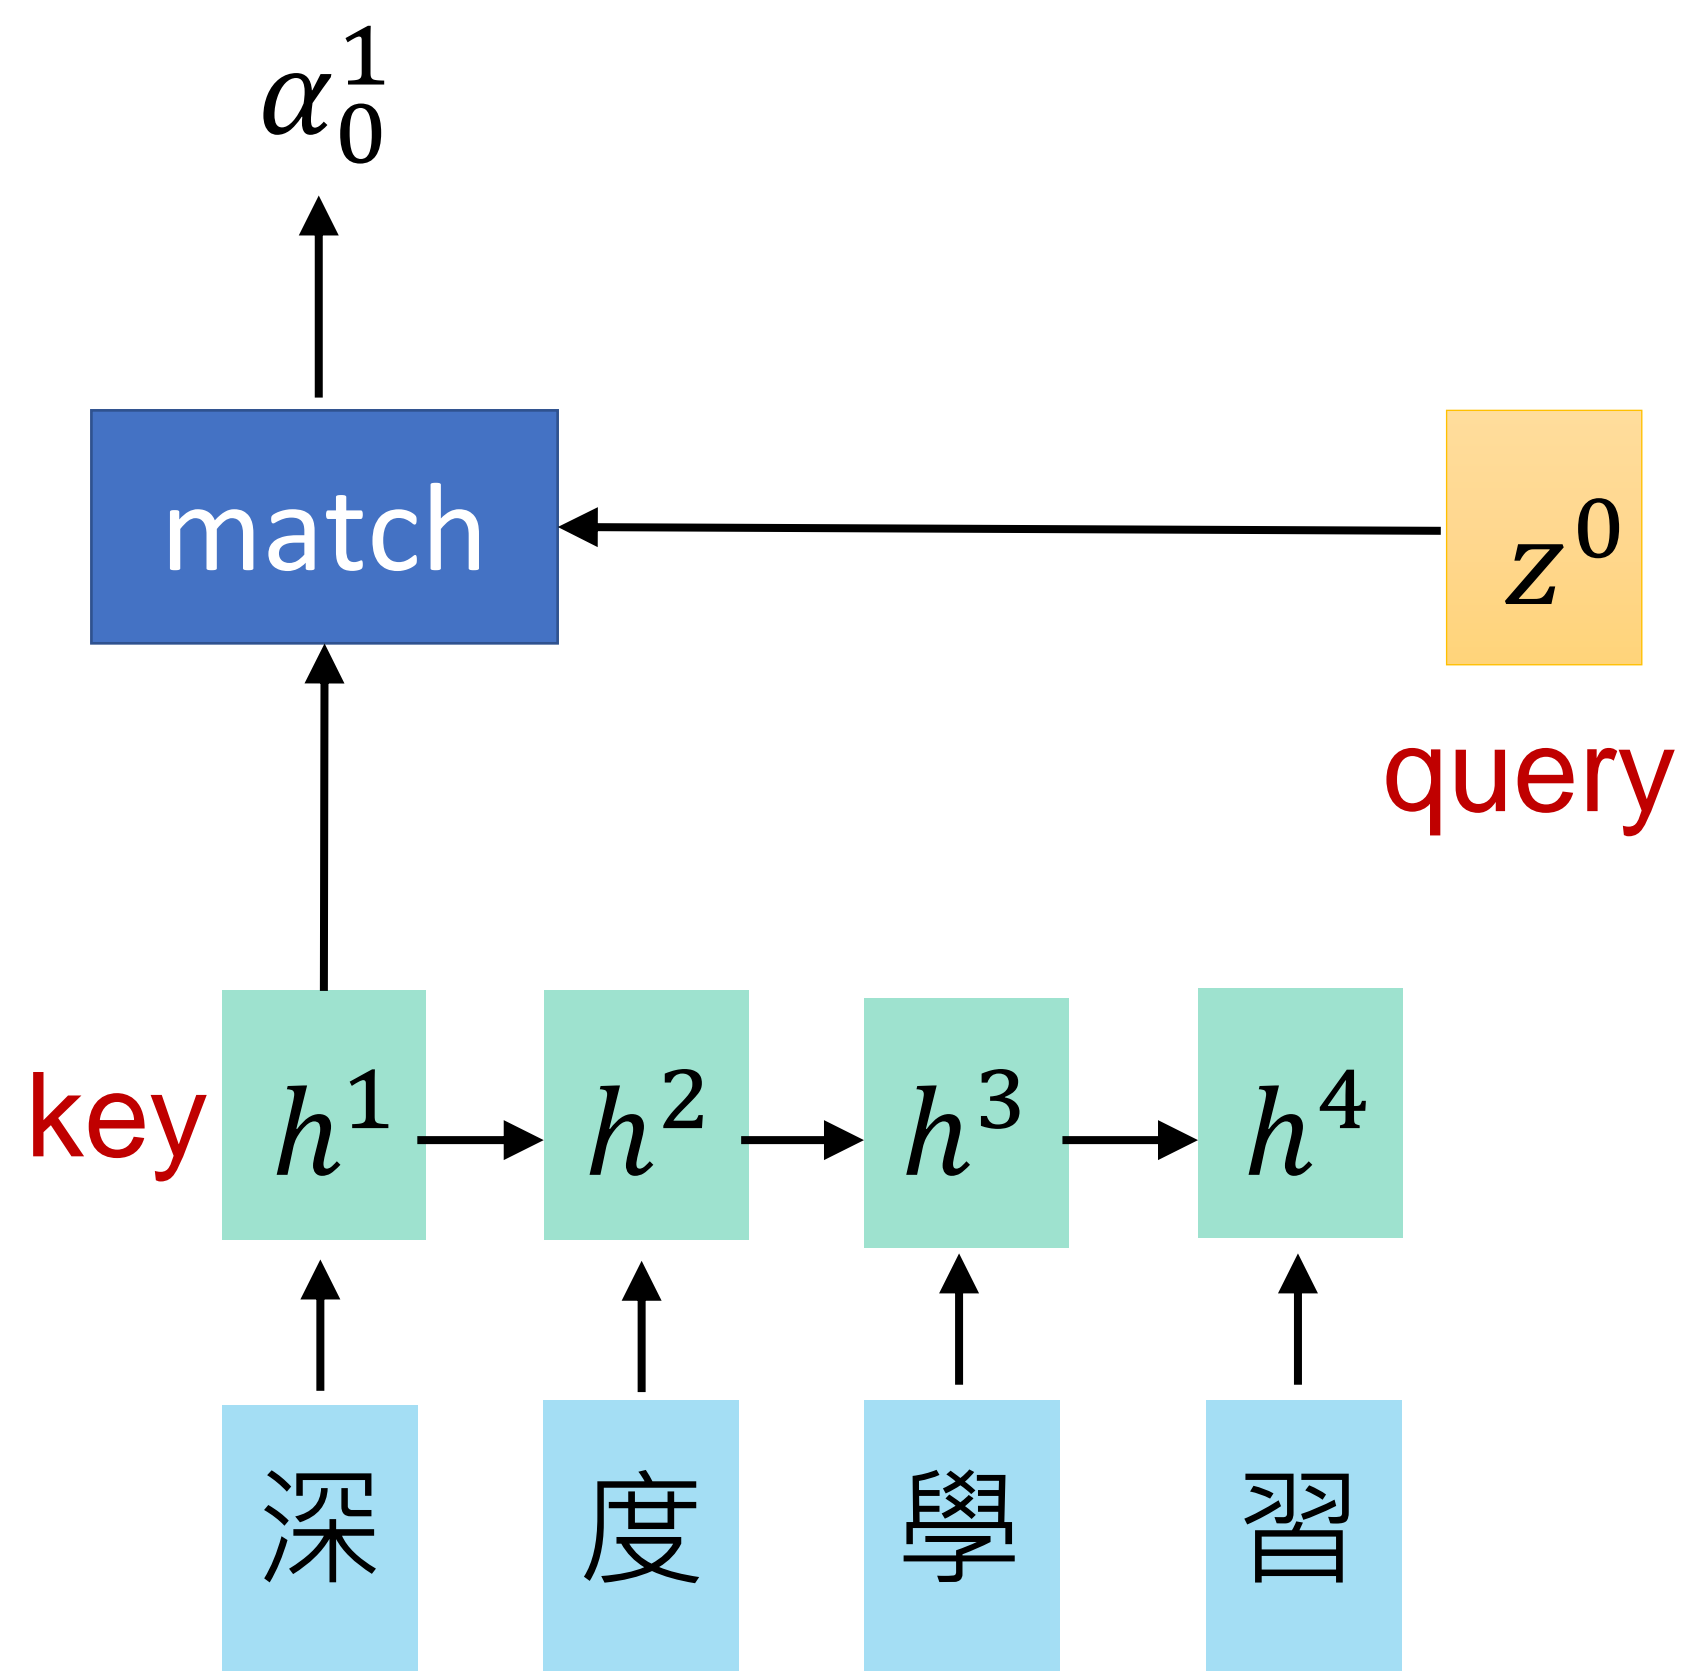

Attention

- Encoder-decoder model is important in **NMT**
- RNNs need **attention mechanism** to handle long dependencies
- Attention allows us to access any state

Basic Attention

Dot-Product Attention

- Input: a query q and a set of key-value (k - v) pairs to an output
- Output: weighted sum of values

Inner product of
query and corresponding key

$$A(q, K, V) = \sum_i \frac{\exp(q \cdot k_i)}{\sum_j \exp(q \cdot k_j)} v_i$$

- ✓ Query q is a d_k -dim vector
- ✓ Key k is a d_k -dim vector
- ✓ Value v is a d_v -dim vector

Dot-Product Attention in Matrix

- Input: *multiple* queries q and a set of key-value (k - v) pairs to an output
- Output: a set of weighted sum of values

$$A(q, K, V) = \sum_i \frac{\exp(q \cdot k_i)}{\sum_j \exp(q \cdot k_j)} v_i$$

$$A(Q, K, V) = \text{softmax}(QK^T)V$$

$$[|Q| \times d_k] \times [d_k \times |K|] \times [|K| \times d_v]$$

softmax
row-wise

$$= [|Q| \times d_v]$$

Multi-Head Attention

- Idea: allow words to interact with one another
- Model
 - Map V , K , Q to lower dimensional spaces
 - Apply attention, concatenate outputs
 - Linear transformation

$$\begin{aligned}\text{MultiHead}(Q, K, V) \\ &= \text{Concat}(\text{head}_1, \dots, \text{head}_h) W^O \\ \text{head}_i &= \text{Attention}(QW_i^Q, KW_i^K, VW_i^V)\end{aligned}$$

42 Scaled Dot-Product Attention

- Problem: when d_k gets large, the variance of $q^T k$ increases

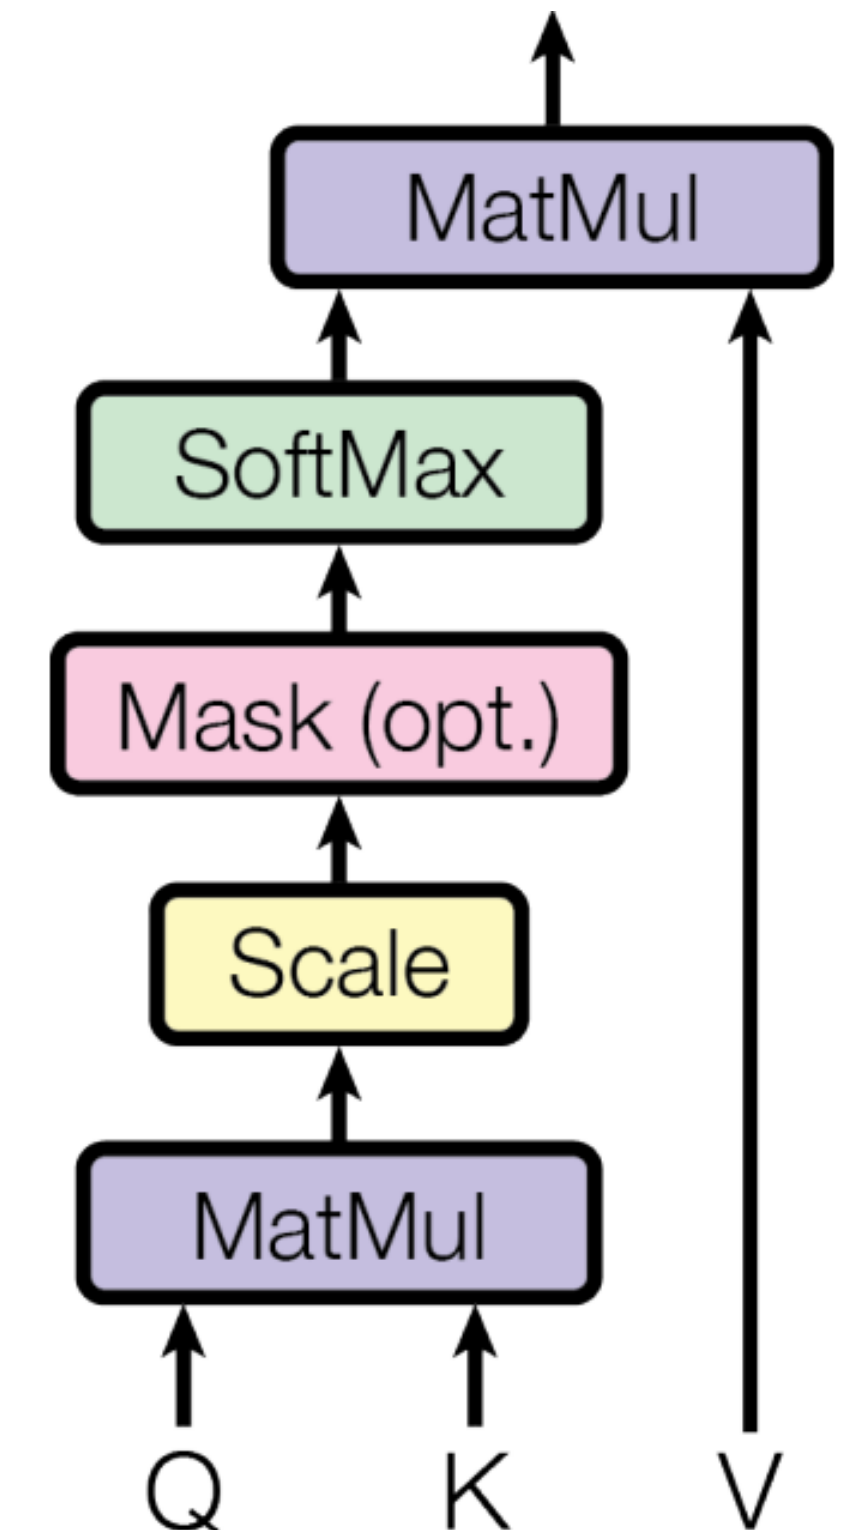

→ q, k are random variables with mean 0 and variance 1
→ $q^T k$ has mean 0 and variance d_k
→ variable 1 is preferred

- Solution: scale by $\sqrt{d_k}$

$$A(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

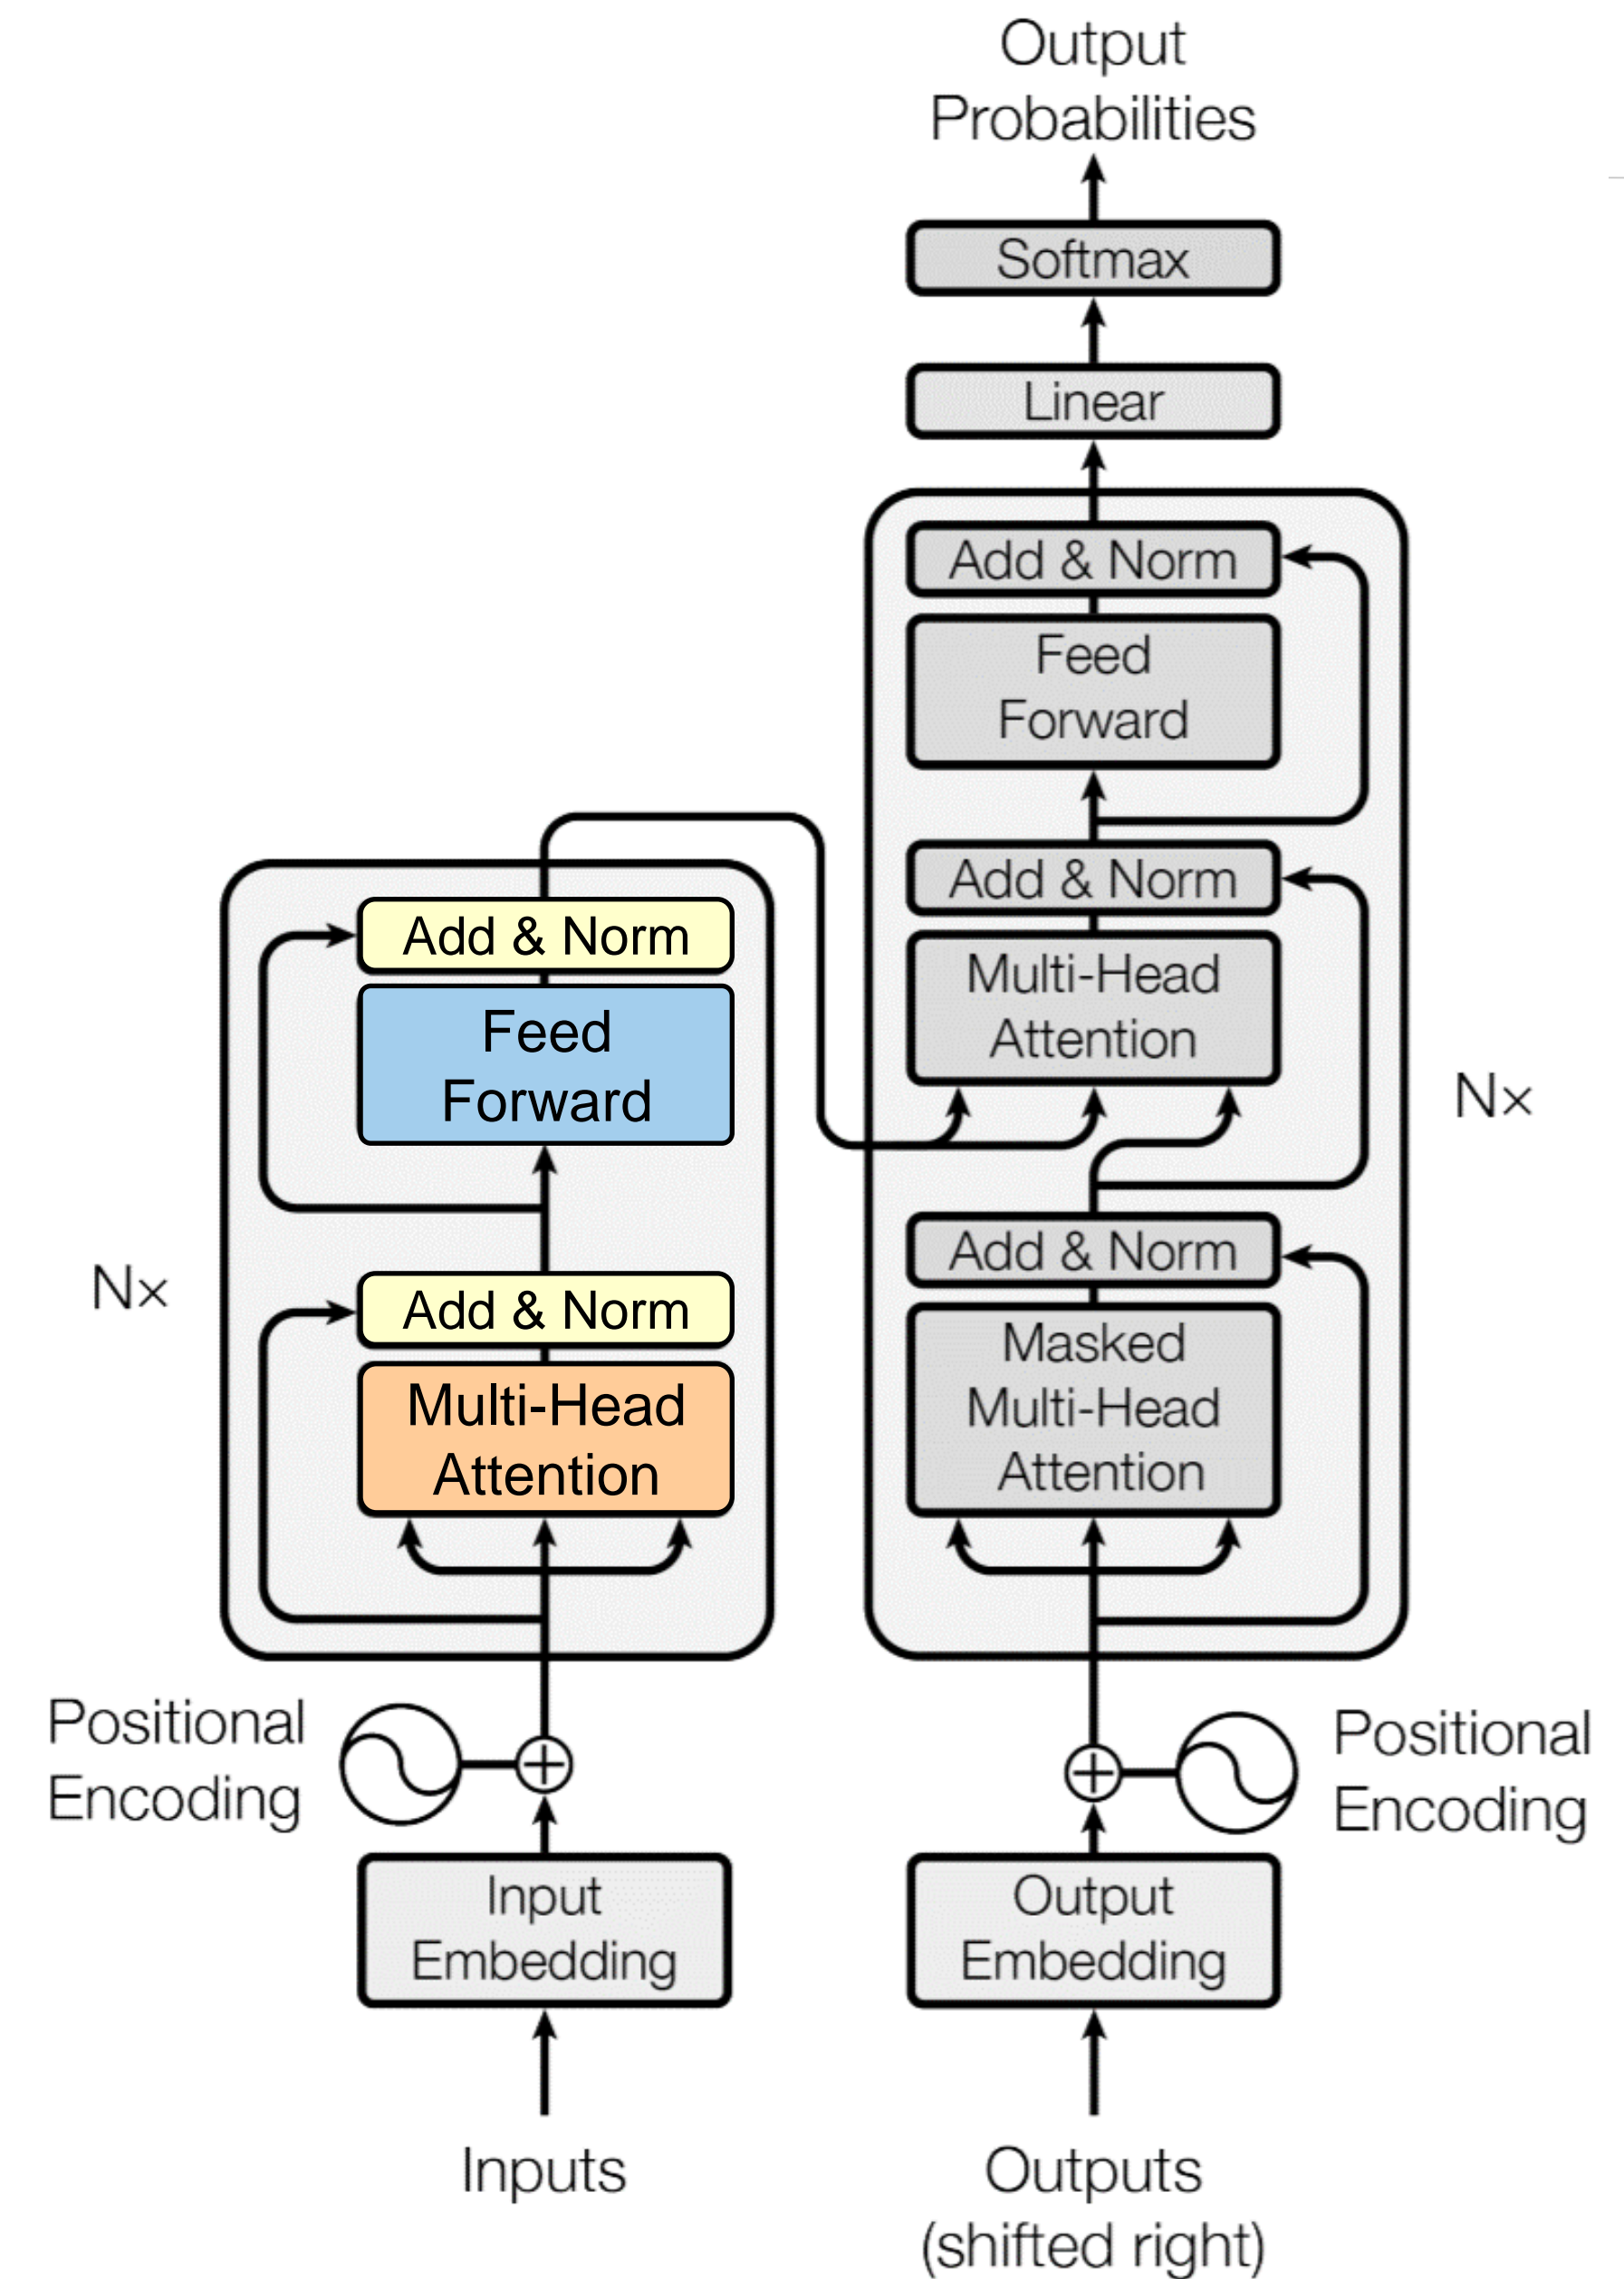

$$A(q, K, V) = \sum_i \frac{\exp(q \cdot k_i)}{\sum_j \exp(q \cdot k_j)} v_i$$

Transformer Encoder Block

- Each block has
 - multi-head attention
 - 2-layer feed-forward NN (w/ ReLU)
- Both parts contain
 - Residual connection
 - Layer normalization (LayerNorm)

$$H(x) = g(x) = x + F(x)$$

Change input to have 0 mean and 1 variance per layer & per training point

→ LayerNorm(x + sublayer(x))

$$\mu^l = \frac{1}{H} \sum_{i=1}^H a_i^l \quad \sigma^l = \sqrt{\frac{1}{H} \sum_{i=1}^H (a_i^l - \mu^l)^2} \quad h_i = f\left(\frac{g_i}{\sigma_i} (a_i - \mu_i) + b_i\right)$$

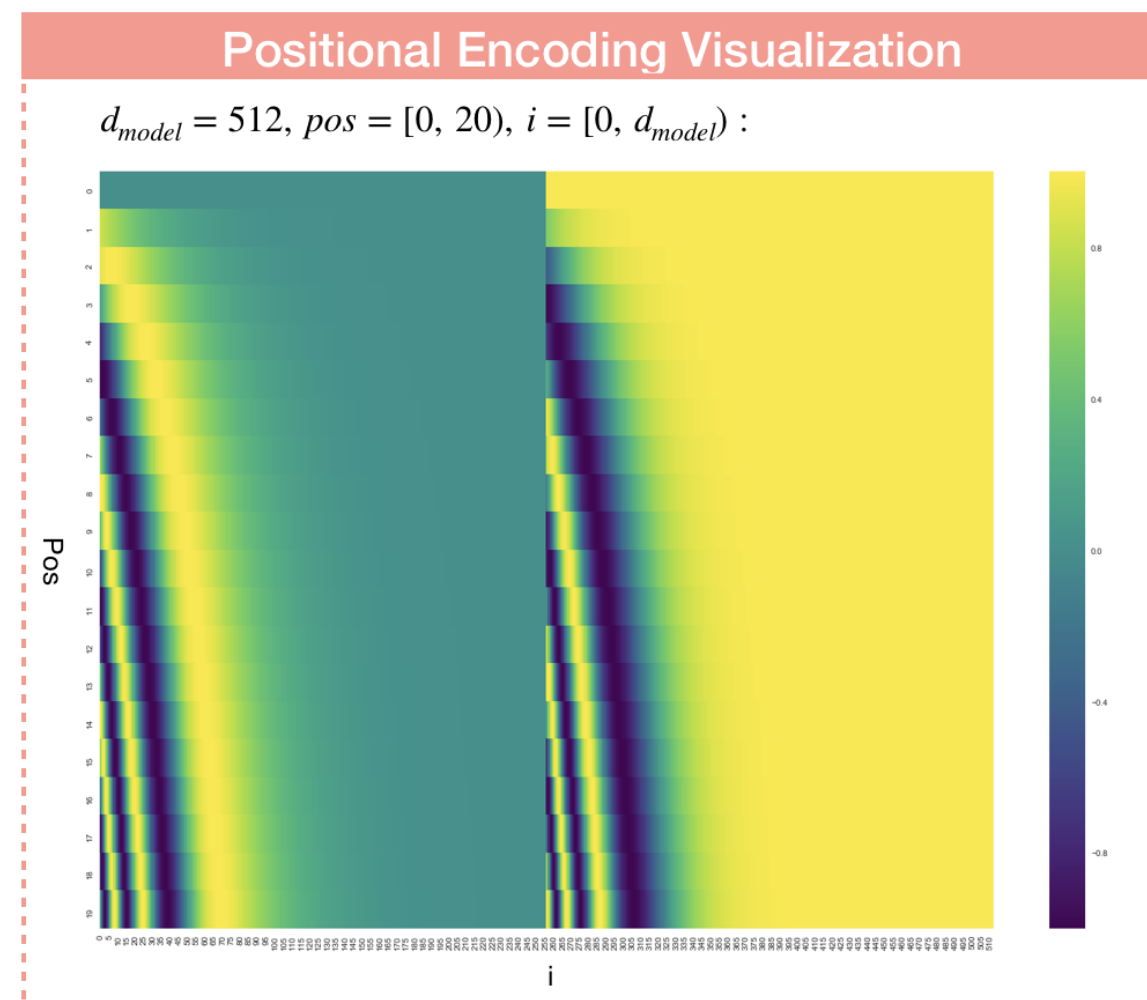

Encoder Input

- Problem: temporal information is missing
- Solution: **positional encoding** allows words at different locations to have different embeddings with fixed dimensions

$$PE_{(pos, 2i)} = \sin(pos/10000^{2i/d_{model}})$$

$$PE_{(pos, 2i+1)} = \cos(pos/10000^{2i/d_{model}})$$

Training Tips

- Byte-pair encodings (BPE)
- Checkpoint averaging
- ADAM optimizer with learning rate changes
- Dropout during training at every layer just before adding residual
- Label smoothing
- Auto-regressive decoding with beam search and length penalties

Concluding Remarks

- **Non-recurrence** model is easy to parallelize
- **Multi-head attention** captures different aspects by interacting between words
- **Positional encoding** captures location information
- Each transformer block can be applied to diverse tasks
